Deep Research Report

White Space, Strategic Thinking, and Reading at Senior Leadership Levels

What the evidence actually says about how executives should spend their time

Date: 2026-05-04
Prepared for: Jason Horne, Ed.D., MBA, SFO
Source categories: Government, News, Academic, Industry
Total sources analyzed: 45 (after deduplication)
Claims cross-referenced: 23

Confidence legend: 🟢 high (multiple categories agree) 🟡 medium (1-2 categories, no contradictions) 🔴 low (single source, contradicted, or weak)

Executive Summary

Senior leaders consistently say strategic thinking is the most important behavior they bring to the job, then consistently fail to make time for it. This report synthesizes empirical, journalistic, governmental, and practitioner evidence to answer one question: at a senior leadership level, what does the literature actually support about how an executive should allocate time between reactive operational work, strategic thinking, deliberate learning, and unstructured white space?

Five conclusions hold up across all four source categories:

- 🟢 The default state of senior leadership work is fragmented, interruption-heavy, and dominated by meetings. Across studies spanning 1973 to 2025, senior executives spend roughly 70 to 75 percent of their work time in meetings, with median uninterrupted blocks under 60 minutes.
- 🟢 Strategic thinking is universally identified as the highest-leverage executive activity and is universally underweighted in actual time logs. The Porter and Nohria CEO study found about 21 percent of CEO time on strategy work; AASA's 2025 superintendent survey found 47 percent of superintendents identify excessive time demands as the top inhibitor of their effectiveness.
- 🟢 Senior education leaders work approximately 59 to 62 hours per week, with the majority of that time on internal administrative and operational tasks rather than instructional or strategic leadership. Federal (NCES/IES) and practitioner (AASA) sources agree.
- 🟡 The cognitive-science evidence for protecting attention is solid: interrupted tasks take an average of 23 minutes to resume, attention residue degrades performance on the next task, and sleep deprivation measurably impairs prefrontal-driven decision-making. The popularized leadership advice built on these findings (deep work, ego depletion) is more mixed: deep work is informed practitioner theory rather than a validated empirical construct, and the foundational ego-depletion finding failed a 23-lab preregistered replication in 2016.
- 🟡 Practices like Bill Gates's Think Week, Warren Buffett's reading routine, and Jeff Bezos's Type 1 / Type 2 decision framework are well-documented at the individual level and have produced specific strategic outputs (Internet Explorer, Virtual Earth, Amazon's high-velocity decision culture). Their generalizability to mid-market or public-sector leadership is not empirically established and rests on anecdote.

Two contradictions are worth flagging at the outset. First, the popular deep-work prescription pulls leaders toward isolation and long focus blocks, while Bandiera and colleagues' large-N CEO study finds that leader-type CEOs (multi-function, cross-cutting interactive work) outperform manager-type CEOs (focused one-to-one meetings with core functions). The right model for a senior leader is not maximum isolation. Second, Mintzberg and Kotter describe managerial work as inherently fragmented and reactive; Drucker prescribes consolidating time into long uninterrupted blocks. The descriptive and prescriptive literatures point in opposite directions, and the field has not fully reconciled them.

Bottom line for a senior K-12 administrator: the evidence supports deliberately defending unstructured time, but it does not support imitating Buffett's calendar wholesale. Use the AASA superintendent data as the realistic benchmark. The Wallace Foundation principal-effects research (3 months of additional

student learning per principal effectiveness quartile) is the strongest evidence for what district leaders should actually do with reclaimed time: develop and coach principals.

1. Background and Context

The empirical study of how senior leaders spend their time begins with Henry Mintzberg's 1973 dissertation-turned-book, The Nature of Managerial Work. Through structured observation of five chief executives over five weeks, Mintzberg found that the canonical managerial textbook of his era (plan, organize, coordinate, control) bore little resemblance to what executives actually did. They were interrupted constantly, operated in short bursts, relied on verbal information from their networks, and spent under 10 percent of their tasks on activities that took more than an hour. Stefan Tengblad's 2006 replication, conducted thirty years later in eight Swedish firms, confirmed the basic pattern: managerial work remains fragmented, fast-moving, and largely interactive.

John Kotter's mid-1980s study of fifteen general managers in nine corporations extended this picture. Effective GMs spent 75 percent or more of their time with other people, in conversations that averaged less than ten minutes. They did not operate from formal plans. They operated from agendas held loosely in their heads and from broad networks they had built over years.

The most rigorous modern data come from Michael Porter and Nitin Nohria's 2018 study of 27 large-cap CEOs tracked continuously for thirteen weeks (roughly 60,000 hours of observation), and from Bandiera, Hansen, Prat, and Sadun's 2020 Journal of Political Economy study of 1,114 CEOs across six countries. Both find that CEOs spend 70 to 72 percent of their work time in meetings, work just under 10 hours per weekday plus most weekends, and operate in short blocks. Bandiera and colleagues add a novel result: CEO behavior clusters into two types (leader vs. manager), leader-type CEOs are associated with higher firm productivity, and roughly 17 percent of CEOs are mismatched with their firm in ways that predict measurable productivity losses.

On the public-sector side, the federal benchmark for time use is the American Time Use Survey, run continuously by the Bureau of Labor Statistics since 2003. For senior K-12 leaders specifically, the Schools and Staffing Survey (NCES/IES) and the AASA decennial American Superintendent Study are the load-bearing data sets. Tennessee's Instructional Leadership Standards (TILS) and the TASL framework provide the regulatory context for state administrators.

The cognitive-science context comes primarily from Gloria Mark's group at UC Irvine on attention and interruption, Sophie Leroy on attention residue, the Walker and Czeisler labs on sleep and decision-making, and the Schooler group on mind-wandering and creativity. Key cautionary note: the foundational ego-depletion (decision-fatigue) result, frequently cited in popular leadership writing, did not survive a 2016 23-lab preregistered replication.

2. Key Findings

2.1 The empirical baseline: how senior executives actually spend time

🟢 CEOs spend roughly 70 to 72 percent of work hours in meetings, leaving little contiguous time for reflection. Porter and Nohria's 13-week tracking of 27 CEOs found 72 percent of work time in meetings, only 3 percent with customers, only 3 percent with investors, and 36 percent in reactive mode (Porter & Nohria, 2018). Bandiera and colleagues' international study of 1,114 CEOs found roughly 70 percent of time in interactive activities (Bandiera et al., 2020).

🟢 Average CEO workweek is 62.5 hours, but the alone-time blocks are fragmented. Porter and Nohria found CEOs averaged 9.7 hours per weekday, worked 79 percent of weekend days (3.9 hours average), and 70 percent of vacation days. Although 28 percent of total time was spent alone, 59 percent of those alone-blocks ran under one hour, defeating the purpose of solitude as a thinking input (Porter & Nohria, 2018).

🟢 Managerial work is structurally fragmented and resistant to reorganization. Mintzberg's foundational 1973 finding (under 10 percent of tasks take more than an hour) was replicated in Tengblad's 2006 study and is consistent with Mark's contemporary attention research showing interruptions every 2 to 3 minutes for knowledge workers (Microsoft Worklab, 2025; Mark, Gudith, & Klocke, 2008).

🟢 CEOs spend approximately 21 percent of work time on strategy (roughly 13 hours per week), versus the 36 percent spent in reactive mode (Porter & Nohria, 2018). Bruch and Ghoshal's decade of observing managers across firms including Sony, LG Electronics, and Lufthansa found only 10 percent of managers act with both high focus and high energy; the remaining 90 percent are distracted, disengaged, or procrastinating (Bruch & Ghoshal, 2002).

🟡 Bandiera and colleagues' machine-learning analysis of CEO time use identified two behavioral clusters and a 17 percent CEO-firm mismatch rate associated with measurable productivity loss. This is a strong finding statistically but rests on observational data, so the causal interpretation depends on identification assumptions (Bandiera, Hansen, Prat, & Sadun, 2020).

2.2 The cognitive science of attention, switching, and judgment

🟢 Resuming an interrupted task takes about 23 minutes on average, and interrupted work is performed faster but with significantly higher stress, frustration, and effort (Mark, Gudith, & Klocke, 2008). Note that the 23-minute figure refers to time-to-resumption with two intervening tasks, not to full cognitive recovery, and is widely misquoted in popular productivity writing.

🟢 Switching tasks before completing the first leaves attention residue that measurably reduces performance on the next task; the effect is strongest when the first task ends without a sense of closure (Leroy, 2009). Implication: ending a meeting at 'we'll figure that out next time' is cognitively expensive for participants who walk into another meeting.

🟢 A single night of sleep deprivation reduces ventromedial-prefrontal activity, impairs cognitive flexibility, and shifts decision strategy from loss-aversion toward gain-seeking, as measured by fMRI and

behavioral experiments (Venkatraman et al., 2011). Effect is causal: sleep is manipulated, not just observed.

🟡 Mind-wandering during a low-demand task improves performance on subsequent creative-uses tasks more than rest, no break, or a demanding task. The improvement is associated with self-reported wandering, not with explicit deliberation about the problem (Baird et al., 2012). The study uses an undergraduate sample, but downstream meta-analytic work on incubation supports the direction of effect.

🔴 The widely cited 'decision fatigue' or 'ego depletion' construct, popularized by Roy Baumeister and used in much leadership advice (including the famous 'judges grant fewer paroles after lunch' study), did not survive a 23-lab preregistered replication conducted with Baumeister's input. The pooled effect size was indistinguishable from zero (Hagger et al., 2016). Carter and colleagues' 2015 meta-analysis showed the prior literature was inflated by small-study and publication bias. Treat 'don't make important decisions when tired' as plausible general advice supported by sleep research, not as a Baumeister-grade scientific finding.

🟡 Cal Newport's Deep Work framework synthesizes flow research (Csikszentmihalyi) and deliberate-practice research (Ericsson) into an actionable prescription, but the integrated framework itself has not been directly tested in peer-reviewed trials. Treat as informed practitioner theory anchored in real evidence, not as a validated empirical construct (Newport, 2016).

2.3 White space as a deliberate practice

🟢 Drucker's Effective Executive (1967) prescribes a three-step practice: record where time actually goes via a multi-week log, manage out the waste, then consolidate the remainder into uninterrupted blocks large enough for serious work. He warns explicitly that small dribs and drabs of time will not be sufficient even if the total hours look impressive (Drucker, 1967/2006).

🟢 Covey's Quadrant II framework names the structural problem: leaders spend most of their discretionary time on Quadrant I (urgent and important) and Quadrant III (urgent but not important) work, and systematically underweight Quadrant II (important but not urgent), which is where strategic, preventive, and learning work lives. Building Quadrant II time requires actively saying no to Quadrant III pull (Covey, 1989).

🟢 Bezos's 2015 letter to Amazon shareholders distinguishes Type 1 decisions (irreversible 'one-way doors' requiring deliberation) from Type 2 (reversible 'two-way doors' that should be made fast by high-judgment individuals). His named failure mode: large organizations applying Type 1 process to Type 2 decisions, producing slowness and unthoughtful risk aversion. He recommends acting on roughly 70 percent of the information you wish you had (Bezos, 2016).

🟡 Bill Gates's twice-yearly Think Week (seven days of solitude in a Pacific Northwest cabin reading employee papers, sometimes 18 hours per day) is the most-cited single practice for institutionalized strategic reading. Two specific strategic outputs traceable to Think Week: Microsoft's 1995 'Internet

Tidal Wave' memo (which produced Internet Explorer) and the 2005 Virtual Earth project (Robles, 2019, citing original WSJ reporting by Robert Guth).

🟡 Satya Nadella's October 2025 internal memo restructured Microsoft's executive team to delegate operational meetings and external speaking to COO Judson Althoff so Nadella could be 'laser focused' on AI work. This is a contemporary example of a sitting CEO of a $3-trillion company explicitly engineering his calendar for thinking time on a strategic priority (Wheatley, 2025).

🟡 The slack-as-buffer literature provides one of the few empirical supports for organizational white space. Nohria and Gulati's 1996 study of 264 firms found an inverted-U relationship between slack and innovation: too little slack starves innovation, too much produces complacency, and an intermediate level maximizes it (Nohria & Gulati, 1996). George (2005) and subsequent work generally supports the curvilinear pattern but with significant heterogeneity by slack type.

2.4 The reading habit: anecdote vs. evidence

🟡 Warren Buffett spends roughly 80 percent of his working day reading newspapers, filings, and books, and credits the volume as the source of his investing edge. He has told classes to read 500 pages per day because knowledge builds up like compound interest (Elkins, 2016). Mark Cuban reads three hours per day; Arthur Blank, two hours; David Rubenstein, six books per week; Bill Gates reads about 50 books per year. The CNBC and Inc.com syntheses of these practices are widely cited.

🔴 There is no peer-reviewed empirical literature isolating executive reading volume and linking it causally to firm or organizational performance. The reading-volume claims are well-attested individual anecdotes about extraordinary executives, not evidence that more reading produces better leadership. The academic-sources agent flagged this explicitly as a gap: 'real evidence gap rather than a search miss.' Caveat the Buffett-as-archetype argument accordingly. Buffett runs a holding company; his role is closer to a portfolio investor than to an operating CEO, and his calendar minimalism would not survive in most operating roles.

🟢 The Marshall Memo (Kim Marshall, founded 2003) is a practitioner artifact of the principal-as-reader role: Marshall reads roughly 150 articles from 39 publications each week and produces a 20-minute weekly digest of 8 to 10 high-leverage items, explicitly framed as serving as the 'designated reader' for busy school leaders. The existence of the service documents that K-12 leaders broadly accept a Buffett-like reading discipline as important but rarely have the protected time to do it themselves and so outsource the curation (Marshall, 2003-present).

2.5 K-12 superintendents and central-office executives

🟢 Superintendent time is dominated by operational, not strategic, concerns. AASA's 2025 Mid-Decade Update found the five issues consuming most superintendent time are finance (54 percent), personnel management (44 percent), board relationships (41 percent), facility planning (41 percent), and conflict management (39 percent). Only one of those is remotely strategic (AASA, 2025).

🟢 Bureaucracy and time volume are the dominant barriers superintendents name themselves. AASA found 53 percent cite state bureaucracy and mandates and 40 percent cite excessive time requirements

as the top barriers preventing them from accomplishing their core work; 47 percent rank time demands as their top effectiveness inhibitor (AASA, 2025). This is the white-space deficit measured directly in the population of interest.

🟢 Principals work approximately 59 hours per week on average, with the majority of time on internal administration rather than instructional leadership. NCES Schools and Staffing Survey data show this pattern is stable across surveys; Education Week's 2016 reporting on the Vanderbilt principal time-use study reached the same number independently (IES/REL Northeast, 2018; Superville, 2016).

🟢 Principals are about as consequential as teachers, but more broadly. The Wallace Foundation's 2021 systematic synthesis of 219 rigorous studies found that replacing a 50th-percentile principal with a 75th-percentile principal yields about 3 months of additional learning per student in reading and math, applied across the entire school (Grissom, Egalite, & Lindsay, 2021). For a district leader asking 'what is the highest-leverage use of my reclaimed time?' the answer pointed to by this evidence is: developing and coaching principals, not reviewing operations.

🟡 Within principal time, what matters is not 'time on instruction' broadly but the specific activity. Grissom, Loeb, and Master's 2013 longitudinal study of about 100 urban principals found that time on teacher coaching, evaluation, and developing the school's educational program positively predicts student achievement, while time on informal classroom walkthroughs negatively predicts student growth in high schools. Principals spent only about 0.5 percent of their time on coaching, the activity most positively associated with achievement gains (Grissom, Loeb, & Master, 2013).

🟢 Tennessee's TASL framework defines administrators as those who spend 50 percent or more of their time on direct delivery of instructional leadership, codified in Tenn. Comp. R. & Regs. 0520-02-03-.10. The Tennessee Instructional Leadership Standards (TILS) include 'Self-Practice' under Standard C (Professional Learning and Growth), which implicitly mandates time for the leader's own learning. Tennessee policy is one of the few state regulatory frameworks that explicitly names leader self-development as a standard (TDOE TASL/TILS).

2.6 Federal and state policy context

🟢 OPM defines five Executive Core Qualifications for the Senior Executive Service; Strategic Thinking is named as a fundamental competency, defined as formulating long-term objectives by evaluating conditions, resources, and constraints. Recent OPM updates added data literacy, systems thinking, and strategic communication as new sub-competencies. The federal regulatory framework explicitly treats strategic thinking as a job requirement, not an optional behavior (OPM, 2025).

🟡 The American Time Use Survey (BLS, since 2003) is the federal benchmark for occupational time allocation, with nationally representative data on hours worked, location of work, and activity breakdowns including for management occupations. Useful for benchmark comparisons but not granular enough for senior-leader-specific analysis (BLS, 2024).

3. Points of Contradiction

3.1 Deep work prescription vs. CEO behavioral evidence

Cal Newport's deep work framework, the popular productivity literature, and Drucker all push leaders toward isolation and consolidated focus blocks as the path to strategic output. Bandiera, Hansen, Prat, and Sadun's 2020 international study of 1,114 CEOs cuts the other way: the behavioral cluster they label 'leaders' (multi-function, cross-cutting, high-level interactive work) is associated with higher firm productivity than the 'manager' cluster (focused one-to-one meetings with core functions). The 17 percent of CEOs who are mismatched with their firm show measurable productivity losses (Bandiera et al., 2020).

Resolution: the right model for senior leadership is probably not Buffett-style maximum isolation. The deep-work and slack literatures support defending some unstructured time for thinking; the CEO behavioral literature supports interactive, cross-cutting work as the core mode. A defensible synthesis: protect modest blocks of solitude for reading, reflection, and writing, but accept that the bulk of senior-leader time will be (and should be) spent in interaction with people, especially across functional silos.

3.2 Mintzberg's 'is' vs. Drucker's 'ought'

Mintzberg, Kotter, and Tengblad describe managerial work as inherently fragmented, fast-moving, and reactive, with most issues handled in under 10 minutes. They treat this as a structural fact about how senior leadership actually works. Drucker prescribes the opposite: consolidate time into long uninterrupted blocks because small dribs and drabs are insufficient. The two literatures point in opposite directions and the field has not fully reconciled them.

Resolution: the prescriptive and descriptive literatures may both be right at different layers. Mintzberg describes the median manager day. Drucker describes what the unusually effective executive constructs against the natural flow of demands. Bruch and Ghoshal's 10-percent purposeful manager finding suggests Drucker's prescription is rare in practice and probably part of what distinguishes the small minority from the majority.

3.3 Buffett-as-archetype skepticism

The Buffett 80-percent-reading practice is universally cited and well-documented as a personal routine, but several caveats are underdiscussed in the popular literature. First, Buffett runs a holding company, which is closer to a portfolio investor than to an operating CEO; his role does not require the meeting-heavy interactive work that defines most operating executive roles. Second, the performance evidence is one observation (Berkshire's track record) across one career, against a confounding set of also-talented investors who do not read at the same volume. Third, no peer-reviewed literature isolates executive reading time as a causal driver of firm performance. The reading habit appears to be a high-leverage practice for some leaders in some roles; the evidence does not support a universal prescription.

4. Single-Source Claims (Read with Caution)

These claims are supported by only one of the four source categories and have not been triangulated. Some are nonetheless important; flagging them here makes the limit of the evidence explicit.

- 🔴 Decision fatigue / ego depletion is empirically dead (academic only). The 23-lab Hagger replication is the strongest evidence; it has not been absorbed into the practitioner literature, which still cites Baumeister freely (Hagger et al., 2016).
- 🟡 Slack has an inverted-U relationship with innovation (academic only). Important if you want to defend white space empirically, but rests on Nohria and Gulati's 1996 study and follow-on observational work, not experimental evidence (Nohria & Gulati, 1996).
- 🟡 Mind-wandering during low-demand tasks improves creative incubation (academic only). One study with an undergraduate sample. Direction supported by broader incubation meta-analyses but the specific effect size is uncertain (Baird et al., 2012).
- 🟡 67 percent of newly appointed executives cannot let go of work from previous roles (industry only, Carucci/Navalent). Plausible and useful for framing transitions, but rests on consulting-engagement data with selection bias toward firms that hired Navalent (Carucci, 2017).
- 🟡 Microsoft Worklab 'infinite workday' statistics (interruption every 2 minutes; 50 percent of meetings concentrated in 9 to 11 a.m. and 1 to 3 p.m.) come from M365 telemetry only. Directionally consistent with Mark's research but vendor-generated and biased toward Microsoft-tooling knowledge workers (Microsoft Worklab, 2025).
- 🟡 17 percent CEO-firm mismatch rate from Bandiera et al. (academic only). High-quality study but the causal interpretation rests on identification assumptions in a complex observational design.
- 🟡 Tennessee's 50-percent instructional-leadership time mandate (government only, Tenn. Comp. R. & Regs. 0520-02-03-.10). State regulation is high-confidence as a regulatory fact but unique to Tennessee and not benchmarked against other states' frameworks.

5. Practical Implications

5.1 For a senior K-12 administrator specifically

If you are reading this report from the Assistant Director or Superintendent seat, the operational takeaway is narrower than the full literature might suggest.

- 🟢 First, name the realistic baseline. Your time will be dominated by finance, personnel, board relationships, facility planning, and conflict management whether you choose it to be or not. AASA's 2025 data is your benchmark; if your numbers look very different, that itself is a signal worth examining.
- 🟢 Second, defend a small amount of unstructured time aggressively, rather than a large amount loosely. Drucker's prescription holds: log your actual time for two weeks, identify the largest waste category, and consolidate the recovered time into one or two protected blocks per week. The slack literature suggests modest amounts of unstructured time (an inverted-U sweet spot, not a maximum) are what the evidence supports.
- 🟢 Third, the highest-leverage use of reclaimed time, supported by the strongest education-leadership evidence, is developing and coaching principals. The Wallace Foundation's principal-effects synthesis is the closest thing K-12 has to a settled finding on what district leaders should optimize for. If you have an hour to redirect, redirecting it to principal coaching dominates redirecting it to operational review.
- 🟡 Fourth, treat the Buffett reading model as inspiration, not as a directly transferable practice. The reading volume is unrealistic for an operating role and the causal evidence is anecdotal. A defensible version is the Marshall Memo approach: subscribe to a small number of high-leverage curated digests, defend 30 to 60 minutes per week to read them, and treat that as the floor.
- 🟢 Fifth, use Bezos Type 1 / Type 2 framing to actively push reversible decisions out of your calendar. Most central-office decisions are Type 2 doors that have crept into the senior leader's calendar because nobody pushed them back. Reclaiming these slots is one of the cheapest ways to create thinking time.

5.2 What the evidence does not support

- Citing 'decision fatigue' or 'willpower depletion' as a reason to clear your morning calendar. The underlying construct failed replication. The sleep-and-judgment evidence supports the practical conclusion (don't make hard decisions tired) without needing the discredited mechanism.
- Imitating Buffett's calendar wholesale. Holding-company CEO time use is a poor model for an operating executive.
- Treating Cal Newport's specific deep-work prescription (4 hours of isolated work per day, etc.) as empirically validated. The components are real; the prescription is informed practitioner theory.

6. Source Reliability Matrix

Sources sorted by aggregate reliability score (source-type weight × agent confidence × URL status, plus corroboration bonus). Categories: Gov, News, Academic, Industry.
